Sex and gender: modifiers of health, disease, and medicine

Franck Mauvais-Jarvis, Noel Bairey Merz, Peter J Barnes, Roberta D Brinton, Juan-Jesus Carrero, Dawn L DeMeo, Geert J De Vries, C Neill Epperson, Ramaswamy Govindan, Sabra L Klein, Amedeo Lonardo, Pauline M Maki, Louise D McCullough, Vera Regitz-Zagrosek, Judith G Regensteiner, Joshua B Rubin, Kathryn Sandberg, Ayako Suzuki

Clinicians can encounter sex and gender disparities in diagnostic and therapeutic responses. These disparities are noted in epidemiology, pathophysiology, clinical manifestations, disease progression, and response to treatment. This Review discusses the fundamental influences of sex and gender as modifiers of the major causes of death and morbidity. We articulate how the genetic, epigenetic, and hormonal influences of biological sex influence physiology and disease, and how the social constructs of gender affect the behaviour of the community, clinicians, and patients in the health-care system and interact with pathobiology. We aim to guide clinicians and researchers to consider sex and gender in their approach to diagnosis, prevention, and treatment of diseases as a necessary and fundamental step towards precision medicine, which will benefit men's and women's health.

The Inclusion of Women in Studies of Occupational Cancer: A Review of the Epidemiologic Literature From 1991–2009

Karin Hohenadel, MSc,^{1*} Priyanka Raj, MPH,¹ Paul A. Demers, PhD,^{1,2} Shelia Hoar Zahm, ScD,³
and Aaron Blair, PhD³

Introduction Since the early 1990s, researchers have been concerned with the low rate

Introduction *Since the early 1990s, researchers have been concerned with the low rate at which women are included in epidemiologic studies of occupational cancer. A previous evaluation determined that one-third of articles published between 1970 and 1990 included women.*

Methods *To assess whether there has been an improvement in recent years, papers on occupational cancer between 1991 and 2009 were reviewed in fifteen journals.*

Results *The proportion of articles that included men remained stable around 90%, while the proportion of articles that included women increased substantially, from 39% in 1991–1995 to 62% in 2006–2009. Articles that assessed risk among men only or men and women presented a higher number of risk estimates and were more likely to evaluate dose-response relationships than studies including women.*

Conclusions *Despite advances in the inclusion of women in studies of occupational cancer, disparities remain in the number of studies of occupational cancer and depth of analysis in studies that included women. Am. J. Ind. Med. 58:276–281, 2015.*

Studying Cancer Among Female Workers: Methods and Preliminary Results from a Record-Linkage System in Italy

In the context of a national program for occupational health surveillance, we examined cancer mortality among women from two study populations. The Torino Longitudinal Study includes 159,039 women, resident in Torino, northern Italy, 18 to 64 years old and economically active at the 1981 census. The Italian Cross-sectional Study includes 2,038 deaths among 6,073,071 Italian women, 18 to 64 years old and economically active at the 1981 census. Preliminary results indicate that women in higher socioeconomic classes showed excess overall cancer mortality. This excess was almost entirely explained by increased breast cancer among teachers, managers, and public officials. Metal, wood, and clothing manual workers showed a significantly increased risk of ovarian cancer. Some excesses of lung and digestive cancers were noticeable among women in the textile and clothing industry and in the restaurant, bar, and hotel trade. Further study is under way.

Studying Cancer Among Female Workers: Methods and Preliminary Results from a Record-Linkage System in Italy

In the context of a national program, we examined cancer mortality among women in the Torino Longitudinal Study and the Italian Cross-sectional Study in northern Italy, 18 to 64 years old and 18 to 64 years old, respectively. Preliminary results indicate that excess overall cancer mortality was entirely explained by increased breast and public officials. Metal, wood, and significantly increased risk of ovarian digestive cancers were noticeable in industry and in the restaurant, bar, and way.

Health and work among women in Italy: An overview of the epidemiological literature

Roberta Pirastu¹, Susanna Lagorio², Lucia Miligi³ & Adele Seniori Costantini³

¹*Department of Animal and Human Biology, Università La Sapienza, Rome;* ²*The Istituto Superiore di Sanità, Rome;* ³*The Center for Study and Prevention of Cancer, Unit of Occupational Epidemiology, Florence, Italy*

Accepted in revised form 6 September 1998

Abstract. The objective of this paper is to give an overview of the epidemiological studies completed in Italy during the past 25 years, about the role of occupational exposures on the development of adverse health effects on women. The implications for research developments are also discussed. The epidemiological investigations of selected categories of work-related health effects published in Italy in the years 1970–1995 were identified from the medical literature databases. The total number of studies is 142, including cohort mortality studies ($n = 12$), case-control studies of different neoplasms ($n = 14$),

investigations of adverse reproductive effects ($n = 8$) and studies of occupational diseases different from the above ($n = 94$). In most investigations, women workers were not the main study objective and hence the number of females under study was small. The conclusion is that in Italy, given the dearth of studies of female workers and the preponderance of women in many economic sectors, i.e. the textile and shoe industry, health care, personal services and schools, there is a need to identify women workers in the above industries and occupations as priorities for epidemiological research and surveillance.

Gender differences in occupational exposure patterns

Amanda Eng,¹ Andrea 't Mannetje,¹ Dave McLean,¹ Lis Ellison-Loschmann,¹
Soo Cheng,¹ Neil Pearce^{1,2}

Methods Men and women aged 20–64 years were randomly selected from the Electoral Roll and invited to take part in a telephone interview, which collected information on self-reported occupational exposure to specific dusts and chemicals, physical exposures and organisational factors. The authors used logistic regression to calculate prevalence ORs and 95% CIs comparing the exposure prevalence of males (n=1431) and females (n=1572), adjusting for age. To investigate whether men and women in the same occupation were equally exposed, the authors also matched males to females on current occupation using the five-digit code (n=1208) and conducted conditional logistic regression adjusting for age.

Results Overall, male workers were two to four times more likely to report exposure to dust and chemical substances, loud noise, irregular hours, night shifts and vibrating tools. Women were 30% more likely to report repetitive tasks and working at high speed, and more likely to report exposure to disinfectants, hair dyes and textile dust. When men were compared with women with the same occupation, gender differences were attenuated. However, males remained significantly more likely to report exposure to welding fumes, herbicides, wood dust, solvents, tools that vibrate, irregular hours and night-shift work. Women remained more likely to report repetitive tasks and working at high speed, and in addition were more likely to report awkward or tiring positions compared with men with the same occupation.

What this paper adds

- ▶ The majority of occupational health and exposure assessment studies have traditionally been carried out in men. Therefore, very few studies have compared the distribution of occupational risk factors between women and men.
- ▶ There are substantial differences in occupational exposure patterns between men and women, and these disparities were observed both between and within occupations.
- ▶ The influence of gender should not be overlooked in occupational-health research.

Conclusion This population-based study showed substantial differences in occupational exposure patterns between men and women, even within the same occupation. Thus, the influence of gender should not be overlooked in occupational health research.

Gender differences in occupational exposure to carcinogens among Italian workers

Alberto Scarselli*, Marisa Corfiati, Davide Di Marzio, Alessandro Marinaccio and Sergio Iavicoli

Conclusions

This study shows significant disparities in the prevalence and level of occupational exposures to carcinogens among female and male workers in the Italian workforce. Moreover, in certain occupational settings women, compared to men, were more likely to be exposed to high levels of carcinogens. The overall findings provide useful information both for decision making in

prevention policies and for programming epidemiological studies on occupational cancer in the female workforce. Likewise, an accurate carcinogenic risk assessment based on concentration levels and co-exposure patterns can help to address prevention and health promotion plans in the workplaces.

Abstract

Background: Many carcinogenic chemicals are still used or produced in several economic sectors. The aim of this study is to investigate differences in occupational exposure patterns to carcinogens by gender in Italy.

Methods: Information about the most common carcinogens recorded in the Italian occupational exposures database (SIREP) for the period 1996–2015 was retrieved. Descriptive statistics were calculated for exposure-related variables (carcinogenic agent, occupational group, economic activity sector, and workforce size). The chi-square(χ^2) test was used to verify differences between genders, and logistic regression analysis was performed to evaluate the association between gender and risk of having higher exposure levels, after adjusting for age. Concurrent exposures to multiple carcinogens were investigated using the two-step cluster analysis.

Results: A total of 166,617 exposure measurements were selected for 40 different carcinogens. Exposed workers were only in a small proportion women (9%), and mostly aged 20–44 years (70%) in both genders. Women were more likely to be exposed than men to higher levels for several carcinogens even after correction for age at exposure, and the exposure level was significantly ($p < 0.01$) associated with occupation, economic sector and workforce size. The five main clusters of co-exposures identified in the entire dataset showed a differential distribution across economic sectors between genders.

Conclusions: The exposures to occupational carcinogens have distinguishing characteristics in women, that are explained in part by work and job segregation. Because of the presence of high-exposed groups of female workers in many industrial sectors, further research and prevention efforts are recommended.

What this paper adds

- Malignant mesothelioma is a rare tumour prevalently due to occupational and environmental exposure to asbestos and the attributable fraction to known sources of asbestos exposure in women is generally much lower than in men;
- In Italy a permanent surveillance system for mesothelioma incidence (ReNaM) is active with 21 463 collected cases in the period between 1993 and 2012 and 16 458 (76.7%) of them investigated for exposure;
- In ReNaM, gender ratio (F/M) is 0.38 and 0.70 (0.14 and 0.30 in the occupational exposed subjects subgroup) for pleural and peritoneal forms respectively;
- Italy presents a larger presence of women among mesothelioma cases due to the relevance of non-occupational exposures and to the historically high female workforce participation in several industrial settings (mainly non-asbestos textile sector);
- The awareness of occupational or environmental origin of mesothelioma in women could improve the efficiency of the public compensation system and the prevention policies, redefining the tools for investigating asbestos exposure in a gender perspective.

Italian pool of asbestos workers cohorts: mortality trends of asbestos-related neoplasms after long time since first exposure

Daniela Ferrante,¹ Elisabetta Chellini,² Enzo Merler,³ Venere Pavone,⁴ Stefano Silvestri,⁵ Lucia Miligi,² Giuseppe Gorini,² Vittoria Bressan,³ Paolo Girardi,³ Laura Ancona,⁶ Elisa Romeo,⁶ Ferdinando Luberto,⁷ Orietta Sala,⁸ Corrado Scarnato,⁴ Simona Mengozzo,⁹ Enrico Oddone,¹⁰ Sara Tunasi,^{1,11} Patrizia Particelli,¹²

Methods Pool of 43 previously studied Italian asbestos cohorts (asbestos cement, rolling stock, shipbuilding), with mortality follow-up updated to 2010. SMRs were computed for the 1970–2010 period, for the major causes, with consideration of duration and TSFE, using reference rates by age, sex, region and calendar period.

Results The study included 51 801 subjects (5741 women): 55.9% alive, 42.6% died (cause known for 95%) and 1.5% lost to follow-up. Mortality was significantly increased for all deaths (SMR: men: 1.05, 95% CI 1.03 to 1.06; women: 1.17, 95% CI 1.12 to 1.22), all malignancies combined (SMR: men: 1.17, 95% CI 1.14 to 1.20; women: 1.33, 95% CI 1.24 to 1.43), pleural and peritoneal malignancies (SMR: men: 13.28 and 4.77, 95% CI 12.24 to 14.37 and 4.00 to 5.64; women: 28.44 and 6.75, 95% CI 23.83 to 33.69 and 4.70 to 9.39), lung (SMR: men: 1.26, 95% CI 1.21 to 1.31; women: 1.43, 95% CI 1.13 to 1.78) and ovarian cancer (SMR=1.38, 95% CI 1.00 to 1.87) and asbestosis (SMR: men: 300.7, 95% CI 270.7 to 333.2; women: 389.6, 95% CI 290.1 to 512.3). Pleural cancer rate increased during the first 40 years of TSFE and reached a plateau after.

Discussion The study confirmed the increased risk for cancer of the lung, ovary, pleura and peritoneum but not of the larynx and the digestive tract. Pleural cancer mortality reached a plateau at long TSFE, coherently with recent reports.

What this paper adds

- Asbestos is a known human carcinogen largely diffused in occupational and environmental setting, nowadays in particular in low-income, middle-income countries.
- We conducted a large cohort study pooling 43 Italian industrial cohorts of asbestos using industries to update mortality analyses in former exposed workers and to study cancer risk after over 40 years of time since first exposure.
- Results in this first report of the project confirm the increased risk for pleural and peritoneal malignancy, lung and ovarian cancer and asbestosis and also suggest an increased risk for bladder cancer, but give little support to the association with other cancers.
- Risk of death for pleural malignancies flattens after long time since first exposure. This result is not compatible with the traditional model which predicts a continuous exponential increase in risk of mesothelioma. These results prompt a revision of the model and have practical implication for prevention, risk apportionment and forecasts of future burden of disease.

Malignant mesothelioma: Ongoing controversies about its etiology in females

Xaver Baur¹  | Arthur L. Frank² | Colin L. Soskolne³ | L. Christine Oliver⁴ | Corrado Magnani⁵

Abstract

Malignant mesothelioma (MM) is one of the most aggressive cancers with the poorest of outcomes. There is no doubt that mesothelioma in males is related to asbestos exposure, but some authors suggest that most of the cases diagnosed in females are “idiopathic.” In our assessment of the science, the “low risk” of mesothelioma in females is because of the nonsystematic recording of exposure histories among females. Indeed, asbestos exposure is mentioned in only some of the studies that include females. We estimate the risk of MM among females to be close to that in males. The absence of detailed exposure histories should be rectified in future studies involving women. As a matter of social justice, the ongoing failure to recognize asbestos as the cause of a majority of cases of MM in females does them, and their kin, a profound disservice.

ILO = International Labour Office; NHL = non-Hodgkin's lymphoma; CLL = chronic lymphocyte leukemia.

* Adjusted by age.

Many of the apparent differences in occupational risks between men and women in this study can be explained by differences in employment patterns. For example, the elevated risks for all malignancies among managers were only observed among males. There were very few women who reported having these occupations, however, and insufficient numbers of exposed cases to provide any meaningful evidence about the magnitude of the risk among women in these occupations. Conversely, HD was elevated among several traditionally female occupations—laundry workers, maids, and hairdressers—for which the number of males was insufficient to estimate effect.

There was evidence for an elevated relative risk of MM among both female and male hairdressers, although in neither gender were the data numerous—there were three female and five male exposed cases.

There is perhaps some evidence of inconsistency in risk of NHL among teachers. Among women, the OR was 1.7 (95% CI = 1.0–2.0, based on 38 exposed cases), whereas among men the OR was 0.7 (95% CI = 0.3–1.3, based on 14 exposed cases). Female teachers appeared to have higher risks of NHL, HD, and to a lesser extent also of leukemia than men and women in other occupations.⁵⁹ Another gender difference appears in the results for textile workers and HD; the ORs were 1.1 for women and 2.4 for men, with equal numbers of exposed cases (11 women and 12 men). MM was elevated among male tailors (OR = 3.5, 95% CI = 1.3–9.6, based on 7 exposed cases), whereas among females it did not appear to be elevated (OR = 0.8, 95% CI = 0.4–1.4, based on 17 exposed cases).

Occupation and Risk of Non-Hodgkin Lymphoma and Its Subtypes: A Pooled Analysis from the InterLymph Consortium

2016

BACKGROUND: Various occupations have been associated with an elevated risk of non-Hodgkin lymphoma (NHL), but results have been inconsistent across studies.

OBJECTIVES: We investigated occupational risk of NHL and of four common NHL subtypes with particular focus on occupations of *a priori* interest.

METHODS: We conducted a pooled analysis of 10,046 cases and 12,025 controls from 10 NHL studies participating in the InterLymph Consortium. We harmonized the occupational coding using the 1968 International Standard Classification of Occupations (ISCO-1968) and grouped occupations previously associated with NHL into 25 *a priori* groups. Odds ratios (ORs) adjusted for center, age, and sex were determined for NHL overall and for the following four subtypes: diffuse large B-cell lymphoma (DLBCL), follicular lymphoma (FL), chronic lymphocytic leukemia/small lymphocytic lymphoma (CLL/SLL), and peripheral T-cell lymphoma (PTCL).

RESULTS: We confirmed previously reported positive associations between NHL and farming occupations [field crop/vegetable farm workers OR = 1.26; 95% confidence interval (CI): 1.05, 1.51; general farm workers OR = 1.19; 95% CI: 1.03, 1.37]; we also confirmed associations of NHL with specific occupations such as women's hairdressers (OR = 1.34; 95% CI: 1.02, 1.74), charworkers/cleaners (OR = 1.17; 95% CI: 1.01, 1.36), spray-painters (OR = 2.07; 95% CI: 1.30, 3.29), electrical wiremen (OR = 1.24; 95% CI: 1.00, 1.54), and carpenters (OR = 1.42; 95% CI: 1.04, 1.93). We observed subtype-specific associations for DLBCL and CLL/SLL in women's hairdressers and for DLBCL and PTCL in textile workers.

CONCLUSIONS: Our pooled analysis of 10 international studies adds to evidence suggesting that farming, hairdressing, and textile industry-related exposures may contribute to NHL risk. Associations with women's hairdresser and textile occupations may be specific for certain NHL subtypes.

Carcinogenicity of night shift work

In June, 2019, a Working Group of 27 scientists from 16 countries met at the International Agency for Research on Cancer (IARC) in Lyon, France, to finalise their evaluation of the carcinogenicity of night shift work. This assessment will be published in volume 124 of the IARC Monographs.¹

Night shift work involves work, including transmeridian air travel, during the regular sleeping hours of the general population. The misalignment or disruption of circadian rhythms of normal physiology is the most pronounced effect of night shift work.

Night shift work is essential for guaranteeing round-the-clock production and activities. It is commonly found in health care, manufacturing, transport, retail, and services sectors. About 1 in 5 workers worldwide are engaged in night shift work; however, definitions, quality, and extent of data vary globally. Regulatory approaches for night shift work and their degree of implementation also differ across regions and employment sectors.

The Working Group concluded there was limited evidence that night shift work causes breast, prostate, and colorectal cancer. This evaluation was based on comprehensive searches of the literature, screening of the studies using established inclusion criteria, and evaluation of study quality, including a standardised review of exposure assessment. Greater weight was given to the most informative human cancer studies based on methodologic considerations, including study size, potential selection bias, night work assessment quality (most notably, potential for misclassification), and control for potential confounding factors. The largest number of informative studies examined breast cancer, several examined prostate and colorectal cancer, while fewer were done on other cancers.

NIGHT SHIFT WORK

VOLUME 124

IARC MONOGRAPHS
ON THE IDENTIFICATION
OF CARCINOGENIC HAZARDS
TO HUMANS

6. EVALUATION AND RATIONALE

6.1 Cancer in humans

There is *limited evidence* in humans for the carcinogenicity of night shift work. Positive associations have been observed between night shift work and cancers of the breast, prostate, colon, and rectum.

6.2 Cancer in experimental animals

There is *sufficient evidence* in experimental animals for the carcinogenicity of alteration in the light–dark schedule.

6.3 Mechanistic evidence

There is *strong evidence* in experimental systems that alteration in the light–dark schedule exhibits key characteristics of carcinogens, based on evidence of effects consistent with immunosuppression, chronic inflammation, and cell proliferation.

6.4 Overall evaluation

Night shift work is *probably carcinogenic to*

Review

Relationship between Night Shifts and Risk of Breast Cancer among Nurses: A Systematic Review

Javier Fagundo-Rivera ¹, Juan Gómez-Salgado ^{2,3,*}, Juan Jesús García-Iglesias ²,
Carlos Gómez-Salgado ¹, Selena Camacho-Martín ⁴ and Carlos Ruiz-Frutos ^{2,3}

5. Conclusions

The different studies of this review showed a significant relation between breast cancer and prolonged rotating night shifts in the established time. In this way, cumulative years working at night, long shift length (12 h), and performing more than 6 night shifts per month for at least 5 years or more are found as a potential breast cancer risk factors, especially in hormone-dependent cancers and among nurses who started working at night in their early career. Similarly, there is a relationship between alterations in certain markers of circadian rhythm such as melatonin or in markers of epigenetic alteration such as telomeres length and breast cancer, that would require further studies in order to support these findings.

Today's world has an increasing and faster trend towards the so-called "24-h societies". To this we must add the need for continuous and necessary care that patients require, so it would be beneficial to apply preventive measures that minimize or avoid as much as possible these alterations in order to reduce the incidence of breast cancer among nurses.

Exposure to benzene and risk of breast cancer among shoe factory workers in Italy

Adele Seniori Costantini¹, Giuseppe Gorini¹, Dario Consonni², Lucia Miligi¹,
Lucia Giovannetti¹, and Margaret Quinn³

Tumori, 95: 8-12, 2009

Aims and background. Evidence of the association between leukemia and benzene exposure has been provided by several epidemiological studies. An increased risk of breast cancer among women exposed to benzene has also been suggested. The aim of this study was to analyze breast cancer risk in a cohort of 1,002 women exposed to benzene in a shoe factory in Florence, Italy, where an excess of leukemia in men was reported.

Methods. The cohort of women at work on January 1st, 1950, was followed from 1950 to 2003 for mortality and from 1985 to 2000 for incidence of breast cancer. For a sub-cohort of 797 women, cumulative exposure to benzene was available.

Results. Standardized mortality ratios were obtained for the 797 women for whom information on cumulative exposure was available. For those with <30 years of latency the standardized mortality ratio was 58.5 (95% CI, 18.9-181.2, based on 3 deaths) and 151.1 (95% CI, 78.6-290.3, based on 9 deaths) for ≥ 30 years of latency. In the >40 ppm-year and ≥ 30 year latency period category, the standardized mortality ratio was 166.0 (95% CI, 62.3-442.2, based on 4 deaths). The standardized incidence ratio for women with a latency period <30 years was 140.9 (95% CI, 75.8-261.9, based on 10 cases) and 108.2 (95% CI, 64.1-182.7) for a latency period ≥ 30 years. For cumulative exposure >40 ppm-years and a latency period <30 years, the standardized incidence ratio was 211.9 (95% CI, 29.9-1504.1, based on 1 case).

Conclusions. The study moderately supports the hypothesis that benzene represents a risk factor for breast cancer.

Occupational Exposure to Solvents and Risk of Breast Cancer

Deborah C. Glass, MA, MSc, PhD,¹ **Jane Heyworth**, BAppSc, MPH, PhD,² **Allyson K. Thomson**, BSc, MSc, PhD,³
Susan Peters, BSc, MSc, PhD,² **Christobel Saunders**, MBBS,⁴ and **Lin Fritschi**, MBBS, PhD³

Background *Occupational exposure to some organic solvents may increase risk of breast cancer.*

Methods *In a population-based case-control study, 1,205 women diagnosed with primary breast cancer between 2009 and 2011 were drawn from the Western Australian Cancer Registry and matched to 1,789 controls from the electoral roll. Exposure to solvents was determined through telephone interviews using OccIDEAS.*

Results *About a third of women were occupationally exposed to solvents. Age adjusted breast cancer risks were elevated for women who had been exposed to aliphatic solvents odds ratio (OR) 1.21 (95%CI 0.99–1.48) and aromatic solvents OR 1.21 (95%CI 0.97–1.52). For most solvents the ORs were higher for those diagnosed before menopause.*

Conclusions *This study suggests that there may be an association between occupational exposure to aliphatic and aromatic solvents and the risk of breast cancer at the low levels of exposure experienced by women in this study. Am. J. Ind. Med. 58:915–922, 2015. © 2015*

Carcinogenicity of polychlorinated biphenyls and polybrominated biphenyls

In February 2013, 26 experts from 12 countries met at the International Agency for Research on Cancer (IARC), Lyon, France, to reassess the carcinogenicity of polychlorinated biphenyls (PCBs) and polybrominated biphenyls (PBBs). These assessments will be published as volume 107 of the IARC Monographs.¹

On the basis of sufficient evidence of carcinogenicity in humans and experimental animals, the Working Group classified PCBs as carcinogenic to humans (Group 1). Additionally, dioxin-like PCBs were also classified in Group 1 on the basis of extensive evidence of an AhR-mediated mechanism of carcinogenesis that is identical to that of 2,3,7,8-tetrachlorodibenzo-para-dioxin, and sufficient evidence of carcinogenicity in experimental animals. However, the carcinogenicity of PCBs cannot be solely attributed to the carcinogenicity of the dioxin-like PCBs.

Role of occupational exposures in lung cancer risk among women

Xu M, et al. *Occup Environ Med* 2020

j  1,2

Methods A population-based case–control study on lung cancer was conducted from 1996 to 2001 in Montreal, Canada. Cases were individuals diagnosed with incident lung cancer and population controls were randomly selected from electoral lists and frequency-matched to age and sex distributions of cases. Questionnaires on lifetime occupational history, smoking and demographic characteristics were collected during in-person interviews. As part of a comprehensive exposure assessment protocol, experts reviewed each subject’s work history and assessed exposure to many agents. The current analysis, restricted to working women in the study, includes 361 cases and 521 controls. We examined the association between lung cancer and each of 22 occupational exposures, chosen because of their relatively high prevalences among these women. Each exposure was analysed in a separate multivariate logistic regression model, adjusted for smoking and other selected covariates.

Results There were few elevated OR estimates between lung cancer and any of the agents, and none were statistically significant, although the limited numbers of exposed women engendered wide CIs.

Conclusions There was little evidence to suggest that women in this population had experienced excess risks of lung cancer as a result of their work exposures. However, the wide CIs preclude any strong inferences in this regard.

Numerosi studi hanno indagato l'esposizione occupazionale per genere osservando sistematiche disparità:

Uomini e donne lavorano in comparti differenti sperimentando esposizioni diverse

- Per esempio le donne che lavorano come impiegate o nei servizi o nel vendite sono circa tre volte che gli uomini (Eng et al 2011) viceversa gli uomini lavorano in settori industriali sono circa un quinto di più delle donne.
- Gli uomini e le donne che fanno lo stesso lavoro percepiscono e/o riportano esposizioni differenti la posizione sociale può influenzare la modalità nel riportare
- Anche all'interno dello stesso lavoro possono avere esposizioni differenti e dal punto di vista epidemiologico questo potrebbe portare ad una misclassificazione dell'esposizione
- Differenti compiti all'interno dello stesso lavoro (es. donne in agricoltura non fanno per lo meno in Italia mansioni di irrorazione pesticidi ma sono maggiormente impiegate nelle mansioni di rientro che comunque possono comportare esposizioni a prodotti fitosanitari)

Nonostante alcuni gap la ricerca epidemiologica sui tumori e lavoro nelle donne sta aumentando

Anche se permangono limiti dovuti al basso numero di donne soprattutto quando si studiano alcuni tipi di tumori

Rimangono problemi legati a come gli studi vengono condotti e analizzati.

Quindi:

Aumentare la numerosità delle donne negli studi

Utilizzare una definizione dell' esposizione che tenga conto delle donne

E considerare confondenti sesso e genere specifici
